There are nine major rivers flowing through Jakarta , the capital city of Indonesia . Total extent of the nine watersheds in Jakarta and its vicinity is about 106 000 ha . Average annual rainfall of 17 stations (1972-1999) throughout the watersheds is 2 973 mm. These make the total water resources throughout Jakarta is about 3.151 billion cubic meters per year (cmy).

Average water demand for evapotranspiration is about 4.5 mm perday or 1 643 mm per year or 1.742 billion cubic meters per year (cmy) throughout the watersheds. Therefore, the total annual available water for storage in the soils, ponds, lakes, reservoirs, vegetations, rivers, and for municipal use will be only 1 330 mm or 1.410 billion cmy.

Water consumption (municipal use) for 11 million people in the nine watersheds is about 1.205 billion cmy or 1 136 mm or 300 liter per capita per day. To meet these requirements the amount of water discharge in the rivers should not be greater than 194 mm or 0.206 billion cmy or 6.52 cubic meters per second (cms) in all nine major rivers. In another words, the runoff coefficient in the whole watersheds should not be greater than 6.5 %.

What is happening in Jakarta is extremely horrible in terms of water problem During rainy seasons maximum daily water discharge in Ciliwung alone (one of the nine rivers) at Rawajati Station is about 103 cms ranging from 20 – 231 cms but in dry seasons minimum daily discharge is only 4.5 cms. These data indicate that the water discharge particularly in rainy seasons is far above it should be, to meet the water requirement for municipal use sufficiently. Because the failure to keep the daily discharge quite low in rainy seasons, many people had been suffering from lacking of fresh water for domestic use. This is the reflection of high runoff coefficient in the watershed. Runoff coefficient in Ciliwung watershed is ranging from 38% to 54%; it is far above it should be. . This high runoff coefficient is the major cause of the very high water discharge or frequent floods in rainy seasons and lacking of fresh water in dry seasons in Jakarta .

It is clear from this analysis that the water problem in Jakarta is not only frequent and high floods in rainy seasons but also lacking of water for municipal use in dry seasons. These situations seem to be more horryfying in the future. Therefore, the water problem in Jakarta needs an extremely great

attention. The key to undertake these problems is a set of activities in an integrated and wholistic watershed management programs.

This paper will discuss analysis and recommendation of integrated watershed management in Ciliwung watershed.

REVIEW AND ANALYZE OF SOME MAXIMAL DISCHARGES IN EUROPE

Ivan Blinkov[1], Velian Jagev[1], V.Al.Stanesku[2]

blinkov@ukim.edu.mk

Some results from the analyzes of data for large water discharge in Europe are presented in this paper. There are 657 data in the database. Some statistical analyzes have been done. A few correlation functions are defined, correlation between maximal water discharge and catchment area Qmax = f (F) and correlation between specific water discharge and catchment area Qsp = f (F).

Firstly, whole database was analyzed. Later, data were classified in classes by their catchment area. - 50 km² ; 50.1<F<100 km² ; 100 .1<F<200 km² ; 200 .1<F<500 km² ; 500.1<F<1000 km² ; 100 0.1<F<2000 km² ; 200 0.1<F<5000 km² ; 5 000.1<F<10000 km² ; 10000. 1<F<50000 km² and >50000.1 km².

The maximal discharge noted in these analyzes was Dounau in Wien happened in august 1501, when Q = 14 000 m 3 /s

The highest specific disharghes noted in the database happened in France on 18.10.1940, when river Canideil on the profile Prats de Molo (F = 11,6 km²) produced 400 m 3 /s or 34.48 m 3 /s.km² .

Also selected data about extreme values were analyzed separately.

There is great level of correlation between data from whole database. The determination quotient was R 2 =0.64.

Analyzes of classified data don't show enough relationship. Extreme values show high level of correlation too.

HYDROMEMETEOROLOGICAL CHARACTERISATION OF THE FLOOD FROM THE PERIOD 14-30 APRIL 2005 IN THE TIMIS-BEGA RIVER BASIN

Jakarta, Indonesia

Abstract

*There are nine major rivers flowing through Jakarta, the capital city of Indonesia. Total extent of the nine watersheds in Jakarta and its vicinity is about 106 000 ha . Average annual rainfall of 17 stations (1972-1999) throughout the watersheds is **2 973** mm. These make the total water resources throughout Jakarta is about **3.151** billion cubic meters per year (cmy).*
*Average water demand for agricultural uses is about 4.0 mm perday or **1 460** mm per year or **1.548** billion cmy throughout the watersheds. Therefore, the total annual retained water as storage in the soils, ponds, lakes, reservoirs, ground water,vegetations, rivers, and for municipal use will be only 1 513 mm or 1.296 billion cmy.*
*Water demand (municipal use) for 11 million people in the nine watershed is about **1.288** billion cmy or **360** liter per capita per day in urban area and 180 liter in rural area. Water demand for industries uses is about 16 million cmy.*
Water loss through floods during rainy seasons is about 1.317 billion cmy due to the increasing runoff coefficient of the watersheds Changing land use and improper agricultural management are likely the main cause of the increasing runoff coefficient.
The losses of water have caused inevitable lacking of water for municipal uses during dry seasons.
It is clear from this analysis that the water problems in Jakarta is not only frequent and high floods in rainy seasons but also lacking of water for municipal use in dry seasons. These situations seem to be worse in the future. Therefore, the water problems in Jakarta need an extremely great attention. The key to undertake these problems is a set of activities in an integrated and holistic watershed management programs.

Key Words : Water resources,Floods, Watershed, Rainfall.

Introduction

Jakarta as capital city of Indonesia has become a metropolitan city like any other capital city in the world. Total population of Jakarta has reached 8.6 million in 2003 with population density about 12 960 people per square kilometer (BPS,2003).
This city has also become the center of business activity; it contributes about 34 % of the total economic activities of Indonesia.
The growing population and business activities have caused a tremendous conversion of agricultural land for houses, shopping centers, schools, offices industrial parks, parking area, highways, and airports. These changing land use is likely become the source of much erosion/sediment, runoff and garbage that fill and

pollutes rivers, drainage channels and reservoirs (ponds, lakes) which in turn causing floods in rainy seasons. On the other side, the changing land use is the main cause of decreasing infiltration and ground water table and in turn causing drought in dry seasons.

The rate of runoff in rainy seasons is increasing due to the decreasing of infiltration rate. Runoff coefficient increase from 0.38 in 1990 to 0.54 in 1996. The increasing runoff coefficient has caused floods more frequently with higher intensity and broader damaged areas. Floods in 2002 inundated 85 locations in Jakarta which covered 16 041 ha (17% of total area), the depth of water logging ranged from 0.2 m to 3.0 m and length of inundation ranged from two hours to 10 days. In the following dry season some areas in Jakarta suffering from extreme lacking of water. There are nine major rivers flowing throughout Jakarta and Ciliwung river is the biggest (Figure 1 and Table 1). Total extent of the nine watersheds about 106 000 ha. Watershed that has a complete hydrological data records is Ciliwung watershed. Therefore, the total water resources and demands of Jakarta will be calculated based on recorded data in Ciliwung watershed.

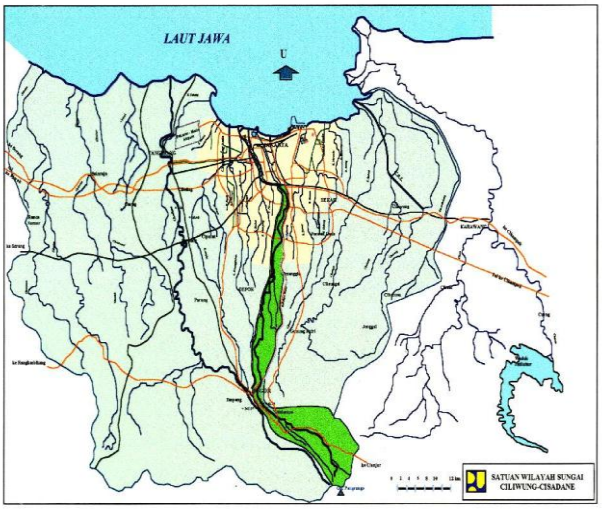

Figure 1. Jakarta and the nine major watersheds.

Table 1. Major Rivers (Watersheds) in Jakarta (NEDECO, 1973)

Rivers/watershed	Area (km^2)	Length (km)	Lowest elevation H^1 (m)	Highest elevation H^2 (m)
Cakung	55	33	6	90
Buaran	30	23	9	45

Angke	263	100	3	220
Total	**1057**			

Water Resources

The total water resources for Jakarta is predicted using rainfall and stream discharge analysis. Rainfall analysis showed that average annual rainfall of 17 stations

throughout the nine watersheds is 2973 mm (Table 2). These make the total water resources for Jakarta is about 3151 billion cubic meter per year (cmy). However, the total water resources in Ciliwung watershed alone will be 951.36 million cmy. Stream discharge analysis showed that monthly water discharge of Ciliwung river is ranged from 16.0 cubic meter per second (cms) in dry seasons to 33.4 cms in rainy seasons with the average of 23.2 cms throughout the year (Figure 2). These make the total water resources in Ciliwung watershed is about 560 million cmy. The ratio of stream discharge to total rainfall, therefore, is 0.59. Using this ratio to the other eight watersheds make the total stream discharge or water resources for Jakarta and its vicinity is about 1750 mm or 1.855 billion cmy. This make the total retained water in the watersheds as water storage in the soils, ponds, lakes, reservoirs, ground water and vegetation is 1.296 billion cmy.

Water Demands

Water demands for societal uses is divided into three major uses: municipal uses, industrial uses, and agricultural uses.
Municipal demand included water for domestic purposes, commercial use, fire protection, street washing, and lawn and garden irrigation. In Jakarta, the municipal uses is provided through municipal water system with the rate of 360 ℓ/capita/day in urban area and 180 ℓ/capita/day in rural area. The capacity of the

municipal water system is only 13.93 cms or 439.296 million cmy make the system can serve only 3.343 million people or 38.8% of the population.
Since the total population of Jakarta and its vicinity in the watershed is about 11 million, which consists of 8.6 million in urban area and 2.4 million in rural area the total demand for municipal uses is about 1.305 billion cmy. Water demand for industrial uses is ranged from 125-1000 cubic meter per day (cmd) for about 88 industries in Jakarta; this make the total water demand for industries uses is about 16 million cmy.
Water demand for agricultural (forest, upland agriculture, paddy rice, garden, etc) is calculated with the assumption of evapotranspiration about 4.0 mm per day; this make the total water demand for agricultural is 1460 mm per year or 1.548 billion cmy. Societal demand for water in Jakarta and its vicinity, therefore, is about 2.852 billion cmy (Table 3).

Table 3. Water Balance in Jakarta and its vicinity

Water Resources (billion cmy)		**Water uses (billion cmy)**	
Stream discharges	0.538	Municipal uses	1.288
Water loss through floods	1.317		
Retained in lake, soil, groundwater, vegetation, reservoirs.	1.296	Industrial uses	0.016
		Agricultural (forest, upland agriculture and paddy rice)	1.548
Available water	**1.824**	**Total**	**2.852**
Total	**3.151**		

Watershed Problems

Floods and water losses

During rainy seasons (Des, Jan, Feb, March, and April) Ciliwung river always causes floods. In recent years, peak discharges of Ciliwung river is increasing (Table 4 and 5). The increasing flood or peak discharge is likely because the increasing runoff coefficient of the watershed. Runoff coefficient is increasing from 0.36 to 0.54 (Table 4) due to the changing land use particularly from forest and agriculture to non agriculture use and the inadequate soil and and water conservation practices in agricultural areas.
The floods not only detrimental to the environment and damage properties but also causing tremendous loss of water. During five months of rainy seasons, water discharge in Ciliwung is about 400 cubic meter or 71% of the total annual discharge. Most of this water cannot be used to meet the societal needs because it flows directly to the sea. Using the same proportion to the other eight rivers, make the total loss of water during rainy seasons in Jakarta and its vicinity is about 1.317 billion cmy.

Drought and Water deficit

Because the failure to keep the loss of water during rainy seasons, many people had been suffering from the lacking of fresh water particularly in dry seasons. Since the total demand for water is much higher that the total supply through the municipal water system, most people take the needed water from the retained water in ponds, lakes, reservoirs, groundwater and rivers. The retained water in those reservoirs is only 1.296 billion cmy but the needed for municipal uses, industries, and agricultural is 2.852 billion cmy (Table.3). Table 3 also indicates that Jakarta and its vicinity have been lacking of water particularly in dry seasons. Because it is impossible to balance the deficit from those reservoirs the Government has tried to transfer some water from Citarum river to Jakarta. The amount of water transfered through West Tarum canal to Jakarta approximately 16.0 cms or 504.6 million cmy. This additional water canot balance the deficit of water completely. Beside this effort, the Government should also set a holistic water resources program in the nine watersheds to prevent the water lost during rainy season through integrated watershed management.

Integrated Watershed Management

It is clear from this analysis that the water problems in Jakarta is not only frequent and high floods in rainy seasons but also lacking of water for municipal use in dry seasons. These situations seem to be worse in the future. Therefore, the water problem in Jakarta needs an extremely great attention. The key to undertake these problems is a set of activities in an integrated and holistic watershed management programs. The integrated watershed management program should be identically with sustainable development program in the watersheds. Therefore, the programs should overcome the problem of frequent

and high floods, the problem of lacking fresh water for municipal use, as well as to increase farmers/community welfare simultaneously.
Focus of the integrated watershed management programs will be to reduce runoff in the whole watershed by increasing infiltration rate and to accommodate the water discharge in a safe manner without flooding. Activities to increase infiltration rate can be carried out through the following activities: integrated and proper land use planning; implementation of conservation farming systems (strip cropping, multiple cropping farming systems including fish and or livestock); implementation of appropriate conservation techniques (mulching, terracing, contour planting, ridge and furrow planting); practicing appropriate soil management techniques (minimum or no tillage, contour tillage, contour planting); spring development; building of grass waterways, diversion ditch, drainage ditch, efficient irrigation systems and building of check dams/water retardance structures or situ (s) in appropriate site.
All of these activities should be planned carefully using appropriate models to determine what to build where and implemented accordingly.

Conclusions

Potential water resources of Jakarta is about 3.151 billion cmy.
Water demand for municipal uses, industries uses and agricultural uses is 2.852 billion cmy. The retained water as water storage in the soils, ponds, lakes, reservoirs, ground water and vegetation is 1.296 billion cmy.
Lost of water through floods during rainy season is 1.317 billion cmy due to changing land use and inadequate soil and water conservation practices.
Jakarta has been deficit of water particularly during dry seasons.
Water problems in Jakarta need an extremely great attention. The key to undertake the problems is a set of activities in an integrated and holistic watershed management programs.
